

Date of report 27 Jun 2019

# Reported case interaction between Cobicistat and Triamcinolone

## **Drugs suspected to be involved in the DDI**

Perpetrator	Daily Dose
Cobicistat	150 (mg)
Dose adjustment performed	Administration Route
No	Oral
Start date	End date
Feb. 4, 2016	Oct. 21, 2016
Victim	Daily Dose
<b>Triamcinolone</b>	Unknown
Dose adjustment performed	Administration Route
No	Other

Start date Sept. 21, 2016

End date Sept. 21, 2017

# **Complete list of drugs taken by the patient**

#### Antiretroviral treatment Darunavir/Cobicistat

Complete list of all comedications taken by the patient, included that involved in the DDI

Triamcinolone (single dose), omeprazol (occasionally)

### **Clinical case description**

Gender	Age
Female	<b>47</b>
eGFR (mL/min) >60	Liver function impairment <b>No</b>

#### Description

This patient was on ART with darunavir/cobicistat monotherapy. She received a local triamcinolone acetonide injection because of shoulder tendonitis. Two weeks later the patient presented with Cushing syndrome. ART was switched to ABC/3TC/DTG. In order to prevent adrenal insufficiency, hydrocortisone replacement was initiated at the same moment when ART was changed. Complete clinical restoration was observed after 4 months. At that moment hydrocortisone dose tapering was initiated and it was completely stopped one month later.

### **Clinical Outcome**

Toxicity

# **Drug Interaction Probability Scale (DIPS)**

Score 7 - Probable

### **Editorial Comment**

This is a nice case of a known DDI that emphasize the role of booster regimens in favoring exogenous Cushing syndrome. The strategy of changing HAART as well as replacing the corticosteroid seem rational and was effective in this patient.

## **University of Liverpool Recommendation**

• These drugs should not be coadministered
